Preface

The *Global status report on road safety* reaffirms our understanding of road traffic injuries as a global health and development problem. More than 1.2 million people die on the world's roads every year, and as many as 50 million others are injured. Over 90% of the deaths occur in low-income and middle-income countries.

Beyond the enormous suffering they cause, road traffic crashes can drive a family into poverty as crash survivors and their families struggle to cope with the long-term consequences of the event, including the cost of medical care and rehabilitation and all too often funeral expenses and the loss of the family breadwinner.

Road traffic injuries also place a huge strain on national health systems, many of which suffer from woefully inadequate levels of resources.

Historically, many of the measures in place to reduce road traffic deaths and injuries are aimed at protecting car occupants. However, as this report shows, nearly half of those killed each year around the world are pedestrians, motorcyclists, cyclists and passengers in public transport; this figure is even higher in the poorer countries and communities of the world.

The *Global status report on road safety* draws our attention to the needs of all road users – including these most vulnerable groups. They too must be considered and given equal priority when policy decisions on road safety, land use and urban planning are made.

Prevention is by far the better option. We have much of the knowledge and experience and many of the tools needed to make our transport systems safe and healthy. Building safer vehicles and roads, designing infrastructure with the protection of pedestrians and cyclists in mind, enhancing public transport and improving our personal behaviour on the roads would reduce injuries and contribute to healthier populations generally.

For these approaches to be realized, there must be collaboration among the actors and agencies within each country whose policies – directly or indirectly – impact on the safety of those on its roads. These partners must use the power of the evidence in hand to encourage those implementing road safety initiatives and adopting and enforcing legislation to align their efforts with best practice from the field.

With the *Global status report on road safety*, we have for the first time an assessment on the status of road safety around the globe. This unique and comparable set of data confirms the relevance of this issue to the societal challenges of today. It identifies clear gaps and opportunities and inspires us to action. Now is the time.

Acknowledgements

The World Health Organization gratefully acknowledges the contributions made to this Report by the following:

WHO headquarters in Geneva: Coordination for the development of this report was provided by Margie Peden. The report was written by Tami Toroyan, country profiles were compiled by Alison Harvey and the statistical analysis was done by Kidist Bartolomeos and Kacem Iaych. Others who contributed to its development were Ala Alwan, Meleckidzedek Khayesi, Etienne Krug, Pascale Lanvers-Casasola, Steven Lauwers, Colin Mathers, Susan Piazza and Laura Sminkey.

WHO African Region: Dieynaba Diallo (Regional Data Coordinator), Olive Kobusingye.

WHO Region of the Americas: Vilma Gawryszewski (Regional Data Coordinator), Eugênia Rodrigues.

WHO Eastern Mediterranean Region: Hala Abou-Taleb (Regional Data Coordinator), Jaffar Hussain, Hala Sakr.

WHO European Region: Manuela Gallitto, Rimma Kuznetsova, Francesca Racioppi, Dinesh Sethi, Francesco Zambon (Regional Data Coordinator).

WHO South-East Asia Region: Salim Chowdhury (Regional Data Coordinator), Chamaiparn Santikarn.

WHO Western Pacific Region: Li Dan, Mayet Darang, Olga Diaz, Hisashi Ogawa, Krishnan Rajam (Regional Data Coordinator).

Country level data could not have been obtained without the invaluable input of:

- The WHO Representatives and staff in countries;
- The National Data Coordinators (see Table A.1 in Statistical Annex);
- All respondents and attendees of the consensus meetings in countries; and
- Government officials who provided clearance of the information for inclusion in the Report.

The report also benefited from the contributions of the following:

- Kelly Henning and Kelly Larson from Bloomberg Philanthropies and Tom Frieden, Health Commissioner from New York City, who provided invaluable technical input.
- Noble Appiah, Grant Baldwin, Matts-Aka Belin, Rita Cuyppers, Michael Fitzharris, Gopalakrishna Gururaj, Maria Isabel Gutiérrez, Adnan A. Hyder, Yohannes Kinfu, Richard Matzopoulos, Dinesh Mohan, Eva Molnar, Andrew Pearce, Ian Roberts, David Silcock, Bjorn Stafborn, Claes Tingvall, Martijn Alexander Vis, David Ward, and Fred Wegman who provided expert advice and review comments;
- David Bramley who edited the Report;
- Susan Kaplan who proofread the Report;
- Graphic designers from L'IV Com Sàrl who produced the design and layout;
- Artist John Sakars for the mural reproduced on the cover and graciously on loan from Centennial Secondary School; photography of mural by Claudia Aubertin-Vedova/Studio Southwest; and
- All the translators who prepared various language versions of this Report.

Finally, the World Health Organization wishes to thank Bloomberg Philanthropies for its generous financial support for the development and publication of this Report.

Executive summary

Over 1.2 million people die each year on the world's roads, and between 20 and 50 million suffer non-fatal injuries. In most regions of the world this epidemic of road traffic injuries is still increasing. In the past five years most countries have endorsed the recommendations of the *World report on road traffic injury prevention* which give guidance on how countries can implement a comprehensive approach to improving road safety and reducing the death toll on their roads. To date, however, there has been no global assessment of road safety that indicates the extent to which this approach is being implemented. This *Global status report on road safety* is the first broad assessment of the status of road safety in 178 countries, using data drawn from a standardized survey

conducted in 2008. The results provide a benchmark that countries can use to assess their road safety position relative to other countries, while internationally the data presented can collectively be considered as a global "baseline" against which progress over time can be measured. *The Global status report* presents a number of key findings:

- Low-income and middle-income countries have higher road traffic fatality rates (21.5 and 19.5 per 100 000 population, respectively) than high-income countries (10.3 per 100 000). Over 90% of the world's fatalities on the roads occur in low-income and middle-income countries, which have only 48% of the world's registered vehicles.

Over 90% of the world's fatalities on the roads occur in low-income and middle-income countries, which have only 48% of the world's vehicles.

Death rates have been declining over the last four to five decades in many high-income countries. Even in these countries, road traffic injuries remain an important cause of death, injury and disability.

- Almost half of those who die in road traffic crashes are pedestrians, cyclists or users of motorized two-wheelers – collectively known as “vulnerable road users” – and this proportion is higher in the poorer economies of the world. For example, while in the high-income countries of the Americas Region 65% of reported road deaths are among vehicle occupants, this situation is very different in the low-income and middle-income countries of the Western Pacific Region where 70% of reported road deaths are among vulnerable road users. The report suggests that not enough is being done to meet the needs of these vulnerable groups. For instance, speed is a key risk factor for injury among pedestrians and cyclists, and yet only 29% of countries meet basic criteria for reducing speed in urban areas, while less than 10% of countries rate the enforcement of their speed limits as effective. Traffic calming measures (particularly where different groups of road users are not separated), infrastructure and policy measures that allow road users to walk and cycle safely, and measures that improve the quality of and access to public transport are also lacking. Many of the measures shown to be effective at reducing road traffic injuries among vulnerable road users can also have other effects on health such as improved respiratory health (as a result of reduced exhaust emissions) and the positive effects associated with increased physical activity.
- The adoption and enforcement of traffic laws appears inadequate in many countries. The development and effective enforcement of legislation is critical in reducing drink-driving and excessive speed, and in increasing the use of helmets, seat-belts and child restraints. This survey showed that fewer than half the countries have laws to address all five of these risk factors, while only 15% have laws that can be considered comprehensive in scope.¹ Over 90% of countries have some kind of national drink-driving law, yet only 49% of countries stipulate a legal blood alcohol concentration limit of less than or equal to 0.05 grams per decilitre, as recommended in the *World report*. Similarly, only 40% of countries have a motorcycle helmet law that covers both riders and passengers, and mandate that helmets should meet a specific national or international standard. Only 57% of countries require seat-belts to be used by passengers in both front and rear seats, and while 90% of high-income countries have a law requiring young children in cars to be restrained with appropriate child restraints, only 20% of low-income countries have similar requirements. Enforcement scores for all these risk factors is generally low suggesting that road safety law enforcement needs to be improved. This requires political will and ensuring that law enforcement agencies are given sufficient human and financial resources to mount sustainable and effective enforcement activities.
- Addressing road safety in a comprehensive manner necessitates the involvement of multiple sectors,

¹ The criteria used to define “comprehensive” in relation to laws on speed, drink-driving, and use of helmets, seat-belts and child restraints are described in the main text.

such as health, transport and police. A coordinated response to the problem includes the development and implementation of a multisectoral strategy on road traffic injury prevention with sufficient finances for planned activities to be achieved within a specified timeframe. While many countries have taken positive steps towards improving the institutional frameworks needed to support road safety efforts, many challenges remain. Only one-third of countries have a national road safety strategy that is endorsed by the government, that includes specific targets, and that has funding allocated for its implementation.

- Finally, the report shows that huge gaps remain in the quality and coverage of the data that

countries collect and report on road traffic injuries. Reliable data on fatalities and non-fatal injuries are needed by countries to assess the scope of the road traffic injury problem, to target responses to it, and to monitor and evaluate the effectiveness of intervention measures. Underreporting of road traffic fatalities remains a big problem in many countries, and the situation is even worse with regard to non-fatal injuries. Furthermore, the lack of harmonization of terminology between countries, and even between sectors within them, limits comparability of data. For instance, varying time periods between the crash and death are used to define a road traffic death, and the definition of a severe non-fatal injury also varies. Just 22% of countries had information on the extent of their

WHO predicts that road traffic injuries will rise to become the fifth leading cause of death by 2030.

road traffic injury problem, the costs incurred by their health sector or their national economies, and the data needed to monitor and evaluate interventions accurately.

There is a growing body of sound scientific evidence on the steps necessary to improve road safety. The last few years have seen an increase in political will in many countries with a number of these measures implemented widely, while road safety has received increasing international attention and support. However, the results presented in this *Global status report* show that much more needs to be done. Key recommendations from this report are:

- Governments need to take into consideration the needs of all road users when making policy decisions that impact on road safety. To date, the needs of vulnerable road users have been neglected in many countries and should be given renewed emphasis, particularly when decisions are made about road infrastructure, land-use planning and transport services.
- Governments need to enact comprehensive laws that require all road users to be protected through enforcement of speed limits that are appropriate to the type and function of the road, through the stipulation of blood alcohol concentration limits to reduce drink-driving, and through the use of appropriate occupant protection measures. Existing legislation should be reviewed and amended to conform with good practices that are based on sound evidence of effectiveness.

- The enforcement of comprehensive and clear legislation with appropriate penalties and accompanied by public awareness campaigns is a critical factor in reducing road traffic injuries and deaths. Enforcement of all road safety laws needs to be both improved and sustained.
- Governments need to ensure that the institutions nominated as responsible for action on road safety are fostering multisectoral collaboration and have the necessary human and financial resources to act effectively.
- Governments need to encourage collaboration between the different sectors involved in collecting and reporting data on road traffic injuries. This involves improving data linkages between police, transport and health services as well as increasing human capacity to undertake data collection.

This *Global status report* shows that no country can afford to sit back and assume that its road safety work is complete. Significant progress in national road safety requires close collaboration between relevant leaders and agencies whose policies – directly or indirectly – impact on the safety of those on the roads. The international community must also play its part in halting and reversing the current global trend of increasing road traffic deaths, by recognizing road traffic injuries as an important health and development problem and by intensifying support for prevention.

1

Background

Road transportation provides benefits both to nations and to individuals by facilitating the movement of goods and people. It enables increased access to jobs, economic markets, education, recreation and health care, which in turn have direct and indirect positive impacts on the health of populations. However, the increase in road transportation has also placed a considerable burden on people's health – in the form of road traffic injuries, respiratory illnesses, and the health consequences that ensue from

a reduction in physical activity. There are additional negative economic, social and environmental consequences that arise from the movement of people and goods on the roads – such as air pollution, greenhouse gas emissions, consumption of finite resources, community severance, and noise.

According to WHO's Global Burden of Disease Project for 2004, road traffic crashes caused over 1.27 million deaths that year – a similar number to

Between 1991 and 2001 the number of motorized vehicles in Thailand almost doubled, from 6.3 million to 11.5 million.

those caused by many communicable diseases (1). Road traffic injuries affect all age groups, but their impact is most striking among the young. Table 1 shows that road traffic injuries are consistently one of the top three causes of death for people aged between 5 and 44 years.

While road traffic death rates in many high-income countries have stabilized or declined in recent decades, data suggest that in most regions of the world the global epidemic of traffic injuries is still increasing. It has been estimated that, unless immediate action is taken, road deaths will rise to the fifth leading cause of death by 2030, resulting in an estimated 2.4 million fatalities per year (1, 2).

In addition to fatalities, many less severe injuries are caused by road traffic crashes: between 20 and 50 million non-fatal injuries are estimated to occur annually around the world (3, 4). These non-fatal injuries are also an important cause of disability (1). A study in Turkey estimated that, of approximately 95 000 people

injured in road traffic crashes in 2005, 13% had a subsequent disability, while in India an estimated 2 million people have a disability that results from a road traffic crash (5, 6). Situations like these have important consequences on the demand for services needed to address disability.

The road traffic injury epidemic also has considerable impact on the economies of many countries, particularly low-income and middle-income countries that are frequently struggling with other development needs. The global losses due to road traffic injuries are estimated to be US\$ 518 billion¹ and cost governments between 1% and 3% of their gross national product – more than the total amount that these countries receive in development assistance (4, 7).

Persons from poor economic settings are disproportionately affected by road traffic injuries, even in high-income countries. For instance, a study in New South Wales, Australia, found that children of relatively

¹ A billion here is used to refer to one thousand million.

Road traffic injuries are one of the top three causes of death for people aged between 5 and 44 years.

Teenage drivers are at increased risk of road traffic crashes.

PHOTO LEFT Those physically disabled as a result of a motor vehicle collision often face stigma and discrimination which can lead to social, educational, occupational and financial deprivation. In addition, many have mental health consequences such as post-traumatic stress disorder, phobias, anxiety and depression.

CENTRE While the figures on road traffic deaths point to the extent of the problem around the world, they fail to tell the full story and to reflect the devastation and suffering that each of these deaths brings to the family, friends and community of those affected.

RIGHT As well as the personal costs, road traffic injuries place a huge demand on health services.

Road traffic injuries show a steep socioeconomic gradient, with those from more disadvantaged backgrounds at higher risk than their more affluent counterparts.

lower socioeconomic status were at highest risk of a road traffic injury (8). Similarly, research from Bangalore, India, found that mortality from road traffic injuries was 13.1 and 48.1 per 100 000 in the poorer socioeconomic groups of urban and rural populations respectively, compared to 7.8 and 26.1 per 100 000 among their more affluent urban and rural counterparts (9). As well as being at increased risk, disadvantaged families are hardest hit by the financial pressure resulting from road traffic crashes. Poor families are less likely to have the financial resources to pay the direct and indirect costs related to a road traffic crash. Many families are driven deeper into poverty by the loss of a family breadwinner, funeral costs, the expenses of prolonged medical care and rehabilitation, or through earnings lost while caring for someone who is injured or disabled (10).

Road traffic injuries place a huge strain on health care services in terms of financial resources, bed occupancy, and

demand placed on health professionals. In Kenya, for example, road traffic injury patients represent between 45–60% of all admissions to surgical wards (11). Similarly, studies in India show that road traffic injuries account for 20–50% of emergency room registrations, 10–30% of hospital admissions, and 60–70% of people hospitalized with traumatic brain injuries (12).

An international response to road traffic injury prevention

The need to reduce road traffic deaths and injuries has been acknowledged by the United Nations system and its Member States for nearly 60 years. Road safety work has been carried out by various global and regional organizations, including the World Health Organization (WHO), the World Bank, the United Nations Regional Commissions, and a number of the regional development banks.

In 2004 the World Health Organization and the World Bank jointly launched the *World report on road traffic injury prevention* (4). This document stressed the role of many sectors in the prevention of road traffic injuries. It also described the fundamental concepts of road traffic injury prevention, the magnitude and impact of road traffic injuries, the major determinants and risk factors, and effective intervention strategies. The *World report* concluded with six recommendations that countries should follow to improve their road safety situation, namely:

1. Identify a lead agency in government to guide the national road traffic safety effort.
2. Assess the problem, policies and institutional settings relating to road traffic injury and the capacity for road traffic injury prevention in each country.
3. Prepare a national road safety strategy and plan of action.

4. Allocate financial and human resources to address the problem.
5. Implement specific actions to prevent road traffic crashes, minimize injuries and their consequences and evaluate the impact of these actions. These actions include measures: to reduce excessive and inappropriate speed; to reduce drink-driving; and to increase the use of motorcycle helmets, seat-belts and child restraints.
6. Support the development of national capacity and international cooperation.

The *World report* promoted a comprehensive approach to road safety which involves identifying the interactions between the road user, the vehicle and the road environment – i.e. the potential areas for intervention. This approach, often called the systems approach, recognizes that the human body is highly vulnerable to injury and that humans make mistakes. A safe road traffic system is therefore one that accommodates and

compensates for human vulnerability and fallibility (Figure 1). To adopt a systems approach necessitates the involvement and the close collaboration of a number of sectors – transport, police, health, industry, civil society, and special interest groups. Fundamental to implementing this approach is the collection of accurate data on the magnitude of road traffic crashes and on risk factors. The countries that have made the most progress in road safety are those that have adopted this comprehensive approach.

In April 2004, soon after the launch of the *World report*, the United Nations General Assembly adopted resolution 58/289 on “Improving global road safety”, which recognized the *World report* and endorsed its recommendations.

The following month, the World Health Assembly adopted resolution WHA 57.10 on “Road safety and health” which called on WHO Member States to prioritize road safety as a public health issue, and to take steps to implement measures that are known to be effective in reducing road traffic injuries. Subsequent United Nations General Assembly resolutions that were adopted in both 2005 and 2008 reinforced the call for Member States to increase the attention paid to road traffic injury prevention in general, and to the implementation of the recommendations of the *World report* in particular.¹ This document reports on the progress made in implementing some of the recommendations of the *World report*.

¹ For the full text of these resolutions, see <http://www.who.int/roadsafety/about/resolutions/en/index.html>.

The need for a global assessment of road safety

As more countries begin or continue to take steps towards addressing their national road safety problem, it has become apparent that regular global assessments of road safety are needed. These are required not only to measure global progress, but also to enable countries to compare their road safety situation with other countries. Such a global assessment requires a standardized methodology that can provide governments, donors, practitioners, planners, and researchers with the information that they need to make evidence-based decisions.

A number of regional mechanisms provide comparable data to assist national policy formulation and drive regional policy.

Examples of such assessments include:

- regular comparisons of road safety performance on a number of indicators in European countries, conducted by the European Road Safety Observatory;
- regional reports on the institutional road safety capacity of member countries, such as those conducted by the Association of Southeast Asian Nations and the Asian Development Bank;
- the International Road Traffic and Accident Database which uses a comparable methodology to collect data on over 500 road traffic variables among 29 member countries;

With an ageing population, high-income countries will need to look again at their road safety strategies to address their vulnerabilities.

- the United Nations Economic Commission for Europe's reviews of legislation on particular risk factors, such as speed and blood alcohol concentration limits; and
- the in-depth road safety assessments conducted by the World Bank in its focus countries.

As well as allowing national developments in the area of road safety to be viewed over time and within an international context, these assessments are essential in providing the data needed to advocate for standardized definitions and measures within regions.

To date, however, no such global assessment of road safety exists. Previous efforts, while informative, have been limited to the analysis of aggregated data on patterns and trends, or have painted a largely illustrative picture by relying predominantly on case studies, or have focused on specific aspects of road safety, rather than providing a set of criteria against which countries are measured regularly (14, 15). In other areas of health and development such assessments are relatively common: the communities working on climate change, development, alcohol, tobacco control and tuberculosis all have tools and indicators that allow them to assess the global status of their particular topic on a regular basis.

Methodology

In August 2007 WHO began to develop the *Global status report on road safety* (GSRRS) to address this data gap and to assess road safety around the world.

The specific objectives of the project were:

- to assess the status of road safety in all WHO Member States using a core set of road safety indicators and a standardized methodology;
- to indicate the gaps in road safety;
- to help countries identify the key priorities for intervention and to stimulate road safety activities at a national level.

A self-administered questionnaire was developed using the recommendations of the *World report* as a basis for its content. The methodology was developed in consultation with an expert committee of road safety researchers and practitioners and was widely reviewed by representatives of international and regional road safety organizations, governmental and

Photo © PAHO

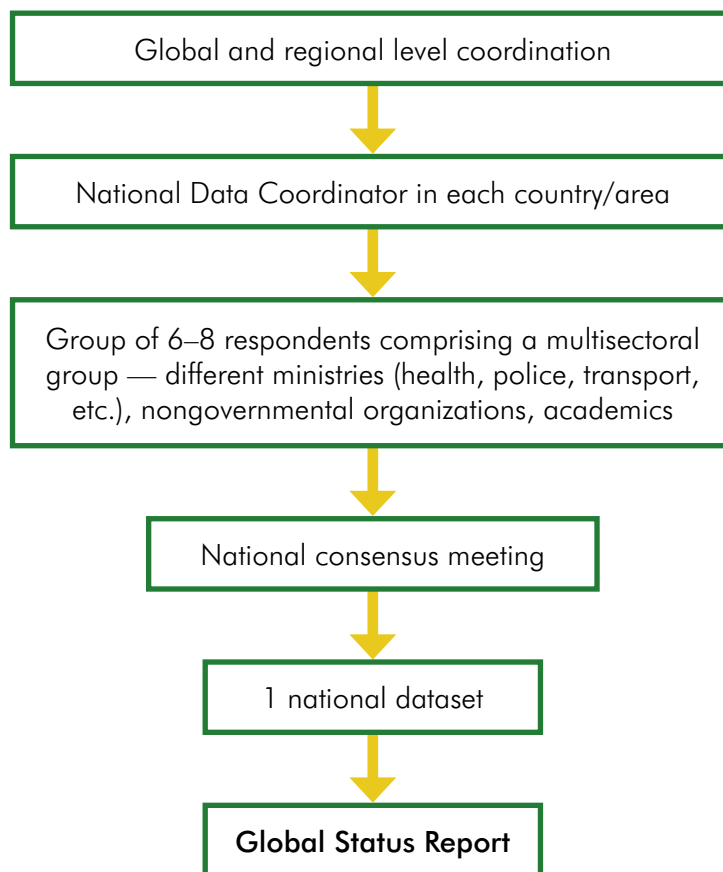

nongovernmental organizations, and academic institutions.¹

The following areas were addressed in the questionnaire:²

- institutional settings and policies (existence of a lead agency on road safety, a national strategy on road safety, and allocation of funding for the activities of both);
- data (road traffic fatalities, non-fatal injuries, data on costs of road traffic injuries);
- exposure to risk (such as the existence of policies to encourage non-motorized modes of transport and public transport and strategies to achieve these, and levels of motorization);
- vehicle and infrastructure standards (the existence of manufacturing standards, requirements for safety audits of road infrastructure projects, and vehicle inspection requirements);
- legislation on some of the main behavioural risk factors (speed, drink-driving, use of motorcycle helmets, use of seat-belts and child restraints, and perceptions of enforcement levels relating to each of these risk factors³);
- pre-hospital care (existence of a formal, publicly available pre-hospital care system, and of emergency access telephone numbers).

The methodology used for data collection is shown in Figure 2. It involved the identification in each participating country of a National Data Coordinator (see Table A.1 in Statistical Annex) who was

Figure 2. Methodology

trained and then facilitated a consensus meeting involving a multisectoral group of up to eight road safety experts. The methodology stipulated that the health, transport and enforcement sectors should be represented among the respondents in each country, while also encouraging the involvement of nongovernmental organizations, academics and other road safety practitioners. Each respondent was asked to complete the questionnaire⁴ independently and then discuss each of the answers at the consensus meeting where the experts would agree as a group on one final country response which was then submitted to WHO.⁵

¹ See Acknowledgements section, page v.

² For the questionnaire and accompanying instruction booklet see www.who.int/violence_injury_prevention/road_safety_status/2009

³ This survey reports “perceptions of enforcement”, as agreed by the group of respondents in the consensus meeting. Note that the eight countries that did not hold a consensus meeting did not answer these questions, while some groups of respondents could not come to a consensus on these scores and so left the enforcement questions blank.

⁴ In the Eastern Mediterranean Region questionnaires were administered during face-to-face interviews.

⁵ More details on the methodology can be found at www.who.int/violence_injury_prevention/road_safety_status/2009

Data collection began in March 2008 and was completed in September 2008, after which the data were validated in a dialogue between WHO staff and the National Data Coordinators to resolve any inconsistencies. Validated data were then sent for government clearance.

Final data were received from 178 participating countries and areas – 176 WHO Member States and Associate Member States, and 2 non-member areas (Table 2). These 178 countries and areas account for over 98% of the world's population.

Most of the data collected through this project are reported in this document. The main text contains an analysis of aggregated information, while the country profiles describe the main variables reported by each participating country using a standard template. The Statistical Annex includes country-by-country results for most variables. Incomplete data and lack of comparability on some variables affected the ability to analyse and report some of the information received from countries.

3

The state of road safety around the world

Road traffic injuries remain a global public health problem

Road traffic injuries remain an important public health problem at global, regional and national levels. While steps are being taken in many countries to improve road safety, much still needs to be done if the rising trend in road traffic deaths is to be halted or reversed.

Over the past few years a range of methods has been used by different organizations to estimate the number of global road traffic fatalities. The WHO Global Burden of Disease project (2004),

which uses vital registration (death certificate) data irrespective of the time period between collision and death, estimates that 1.27 million people died as a result of a road traffic collision in that year (1). The total number of deaths reported in this survey is approximately 660 000 (using a 30-day definition), indicating vast underreporting. When these data are modelled (see Statistical Annex) the total 30-day number for the 178 countries included in the study is 1.23 million. Almost all data sources show that about three-quarters of road traffic deaths are among men and that the highest impact is in the economically active age ranges.

Figure 3. Population, road traffic deaths^a, and registered motorized vehicles, by income group

^a 30-day definition, modelled data.
HIC = high-income countries; MIC = middle-income countries; LIC = low-income countries

Low-income and middle-income countries have the highest burden and road traffic death rates

Most (91%) of the world's fatalities on the roads occur in low-income and middle-income countries, which have only 48% of the world's registered vehicles.

Approximately 62% of reported road traffic deaths occur in 10 countries – which in order of magnitude are India, China, the United States, the Russian Federation, Brazil, Iran, Mexico, Indonesia, South Africa, and Egypt – and account for 56% of the world's population. However, based on modelled numbers, the 10 countries with the highest number of deaths are: China, India, Nigeria, the United States, Pakistan, Indonesia, the Russian Federation, Brazil, Egypt and Ethiopia (see Table A.2 in Statistical Annex). While the total number of deaths is clearly related to both the population and motorization levels within a country

and does not give an assessment of risk, it nonetheless gives an indication of where intervention could help significantly to reduce the total number of road traffic deaths at a global level.

From a public health perspective and for the purpose of making comparisons, the use of rates per 100 000 population is a more useful measure of the size of a problem than absolute numbers, and is also useful for assessing performance over time and for giving an indication of risk. As well as accounting for the highest absolute burden of road traffic deaths, fatality rates relative to population are also highest in low-income and middle-income countries (Table 3).

It is evident that, although the highest rates are in low-income and middle-income countries, road traffic injuries remain very relevant to high-income countries as well. A number of high-income countries have

Over 90% of the world's fatalities on the roads occur in low-income and middle-income countries, which have less than half of the world's vehicles.

Table 3. Modelled road traffic injury fatality rates (per 100 000 population),^a by WHO region and income group

WHO REGION	HIGH-INCOME	MIDDLE-INCOME	LOW-INCOME	TOTAL
AFRICAN REGION ^b	—	32.2	32.3	32.2
REGION OF THE AMERICAS ^c	13.4	17.3	—	15.8
SOUTH-EAST ASIA REGION ^b	—	16.7	16.5	16.6
EASTERN MEDITERRANEAN REGION	28.5	35.8	27.5	32.2
EUROPEAN REGION	7.9	19.3	12.2	13.4
WESTERN PACIFIC REGION	7.2	16.9	15.6	15.6
GLOBAL	10.3	19.5	21.5	18.8

^a 30-day definition.

^b No high-income countries.

^c No low-income countries.

Figure 4. Trends in road traffic fatality rates in selected high-income countries

road traffic injury fatality rates well above the average for this income group. For instance, high-income countries in the Eastern Mediterranean Region have a modelled road traffic injury fatality rate of 28.5 per 100 000 population, which is well above the global average for countries in this broad income group, as shown in Table 3. Similarly, while a number of high-income countries have managed to reduce their road traffic fatality rates in recent decades, in other high-income countries the downward trends in road traffic fatalities that began

in the 1970s and 1980s have started to flatten, suggesting that extra steps are needed to reduce these rates further (see Figure 4).

The 10 countries with the lowest modelled road traffic fatality rates are almost all high-income countries, where rates vary between 3.4 and 5.4 deaths per 100 000 population. While these countries, the Netherlands, Sweden and United Kingdom for instance, may be top performers globally with regard to road safety, they too still have considerable

Photo © P. Venter, GRSP

Pedestrians, cyclists, and drivers of motorized two-wheelers and their passengers account for almost half of global road traffic deaths.

room for improvement. For example, road traffic injuries are still an important cause of death in Sweden, despite a relatively low rate of road traffic fatalities and the successful implementation of a comprehensive approach to the problem. In Sweden, road traffic crashes are responsible for 20% of deaths of children aged between 5 and 19 (16). Similarly, the road transport system in Sweden is responsible for many more deaths – notably of children and young adults – than other forms of transport such as aviation or rail travel. Thus, even countries which appear to be performing well at the global level have a long way to go to achieve a truly safe road transport system.

Nearly half of those dying on the world's roads are vulnerable road users

In most low-income and middle-income countries the majority of road users are vulnerable road users – pedestrians, cyclists, and those using motorized two- or three-wheelers. These groups of road users do not have a protective “shell” around them and are therefore more at

risk than those in vehicles. Public transport users may also be vulnerable road users, particularly where public transport vehicles are unsafe, overcrowded or unregulated (see Box 1).

Vulnerable road users are at additional risk where their needs have not been taken into consideration during the planning of land use or road construction. In many countries roads are planned and built to allow motor vehicles to travel faster while insufficient thought is given to the needs of pedestrians and cyclists, which means that these vulnerable road users face increasing risks in using and crossing the roads (17, 18).

This global survey shows that pedestrians, cyclists, and riders of motorized two-wheelers and their passengers account for around 46% of global road traffic deaths.¹ Vulnerable road users make up the highest reported proportion of total deaths in the South-East Asia and Western Pacific regions (Figure 5). Within regions the proportion of deaths among

¹ If users of unsafe public transport are included as vulnerable road users then this figure of 46% is likely to be an underestimate: in this survey data on public transport fatalities was not collected separately from data related to other four-wheeled vehicles.

Box 1: Unsafe public transportation

Overcrowded and unsafe modes of public transport contribute to road traffic injuries and deaths, particularly in low-income and middle-income countries. Choice of transport modes is frequently related to socioeconomic status, with those who can afford it avoiding these unregulated and unsafe vehicles. A study in Kenya found that buses and *matatus*^a are the vehicles most frequently involved in fatal crashes and that passengers in these vehicles account for 38% of the total road deaths (11, 19). This may be explained in part by deregulation in the public transport market without concurrent regulations on safety measures. In Sri Lanka, for example, public transport buses are either owned by the government or privately owned, with studies showing an increased risk associated with travel on privately-owned buses. Government buses are maintained by the Ministry of Transport and regulated to ensure safety, while regulations are much less stringent for private owners running parallel public bus services. For instance, there are almost no restrictions on driver eligibility or on the maintenance of privately operated public transportation vehicles (20).

While liberalization of the public transport market can increase the supply of vehicles, protection of public safety needs to be an essential feature of this market. Maximization of profits must not be allowed to lead to a reduction in safety standards.

^a *Matatus* are small-scale public transport service vehicles in Kenya.

Figure 5. Reported deaths by type of road user (%), by WHO region and income group^a

^a See Table A.2 in Statistical Annex for information on WHO regions and income level classifications. HIC = high-income countries; MIC = middle-income countries; LIC = low-income countries

PHOTO TOP Poor infrastructure and lack of pavements, and lighting are among the reasons why pedestrians have to share the roads with cars, buses, taxis and other modes of transportation.

PHOTO BOTTOM Police enforcement and automatic speed enforcement are highly effective measures used to enforce speed limits.

vulnerable road users varies considerably. In the South-East Asia Region, for instance, vulnerable road users are reported to account for over 80% of those killed on the roads in Thailand, while in neighbouring Myanmar the figure is 51%. In Colombia, Guatemala and Peru over 70% of fatalities are among vulnerable road users while in other countries of the region – such as the Dominican Republic, Honduras or the United States – the proportion is considerably lower at less than 25%.

Results of this survey suggest that as motorization increases globally many countries are not giving sufficient attention to the needs of vulnerable groups of road users in their transport policies. Many of the proven interventions being implemented globally – such as use of seat-belts and child restraints, vehicle standards, and crash tests – are relevant to car occupants. More research is needed on interventions that address vulnerable road users, while land use planning and road design should also take the needs of these road users into consideration.

Photo © PHHO

Reducing speed will have an impact on both vehicle occupants and vulnerable road users. Setting and enforcing appropriate speed limits is essential. This survey showed that only 9% of countries rate their speed enforcement as more than 7 on a scale of 0 to 10 (see page 20).

Reducing exposure to the risk of injury or death on the road can also be achieved by reducing the total amount of motorized road transport. This in turn requires considerable investment in infrastructure that allows pedestrians and cyclists to walk and cycle safely (see Box 2).

Photo © G. Blakeley/BigStockPhoto.com

Reducing the volume of traffic on roads being used by vulnerable road users can also reduce exposure to the risk of a crash occurring, provided that low speeds can be maintained. Policy-makers need to address the ability of road users to walk and cycle safely, ensure the availability of affordable and safe public transport, and seek ways to reduce dependency on the use of private cars. This survey found that only one-third (32%) of the world's countries have national or local policies that promote walking and cycling as an alternative to motorized transport. Forty-four per cent of countries do not have policies (either national or local)

Box 2: Land use and transport planning

Prioritizing the needs of vulnerable road users includes recognizing the importance of the built environment when making political and planning decisions. Some of the solutions lie in appropriate modifications to the physical road environment and setting up a supportive policy framework rather than focusing only on human behaviour as the primary cause of road traffic crashes. The examples presented below show efforts in four settings to incorporate the needs of vulnerable road users in planning for land use and transport.

Bogota, the capital of Colombia, implemented land use and transport measures intended to meet the needs of the city's non-motorized road users and to improve public transport in the period 1995–2001. The measures included: building specific cycling and pedestrian-only routes, including a car-free route; excluding cars from the city centre at peak times in the morning and afternoon; developing a high-capacity bus system at a cost of US\$ 300 million that carries about 700 000 people a day. These measures contributed to reducing the number of road traffic fatalities from 1387 in 1995 to 697 in 2002. They also improved access to jobs and created a more liveable urban environment (14, 17, 21).

Sweden's model of road safety is frequently cited as good practice. The "Vision Zero" road safety policy adopted in the late 1990s is based on an understanding that the environment needs to be modified to take account of humans' lack of tolerance to mechanical forces and

the human tendency to make errors. Sweden's sustainable road strategy thus aims to modify the environment while protecting road users from unacceptable levels of risk. As well as building bicycle and pedestrian lanes, tunnels and car-free play areas, other environmental solutions are being implemented to separate and protect these road users. Where road users cannot be separated, the strategy acknowledges the need to give pedestrian safety priority over car traffic – particularly by reducing speed.

Delhi, India, has recently completed the first phase of a corridor with segregated pedestrian, bicycle and bus lanes on a major arterial road of the city. The pedestrian lane has been designed with due concern for the needs of the elderly, children and physically-challenged persons. Since street vendors are an integral part of urban streets in Delhi, special consideration has been given to providing space for them without disturbing the flow of bicycles and

pedestrians. In the first 10 months of operation there were no car, motorcycle or bicycle fatalities in the corridor (22).

Lagos, Nigeria, is the sixth largest city in the world with a population of 17 million people. For years, the city has grown rapidly and struggled without reliable public transportation. The public transport system largely consists of minibuses and taxi motorcycles, many of which are not roadworthy and contribute substantially to pollution and road traffic crashes. In 2002, the state government created an agency called the Lagos Metropolitan Transport Authority (LAMATA) with the mission to "transform the state transport system by facilitating an enabling environment". One initiative of LAMATA and the state government was the development of a bus rapid transit system which was completed and launched in March 2009. This system provides Lagos commuters with a clean, affordable, reliable and safe means of getting around the city (23, 24).

Cable barriers are used in a number of high-income countries and have been shown to be cost effective at reducing head-on collisions on highways.

Designed spaces for street vendors in Delhi, India, are part of a new initiative that gives road space to different groups of vulnerable road users.

Bogota's high-capacity bus system.

Only 9% of countries report their enforcement of speed limits as over 7 on a scale of 0 to 10.

that encourage *public transport* as an alternative to car transport, reflecting a similar neglect in meeting the needs of non-motorized road users (see Table A.7 in Statistical Annex). These figures are perhaps surprising given that decreased dependency on the use of private cars can have other positive impacts such as improved respiratory health (as a result of less transport-related air pollution) and reduced levels of obesity (as a result of more physical activity associated with walking and cycling).

Few countries have comprehensive road safety laws that are well enforced

Enacting and enforcing legislation on a number of risk factors for road traffic injuries and deaths is critical in influencing exposure to risk, crash occurrence, injury severity, and post-crash injury outcomes. Comprehensive and clear legislation, enforced with appropriate penalties and accompanied by public awareness campaigns, has been shown to be a critical factor in reducing road traffic injuries and deaths associated with speed, drink-driving, and the non-use of occupant protection measures (helmets, seat-belts, and child restraints). The results of the global survey suggest that the legislation on these risk factors is not comprehensive in many countries, and enforcement is often lacking. Similarly, many countries lack the institutional mechanisms and resources that would allow them to implement planned activities in a coordinated fashion – including adopting and enforcing laws – which may result in a “piecemeal” approach to road safety efforts that is seen in many countries (see Box 3).

Speed

What is known?

- An increase in average speed is directly related both to the likelihood of a crash occurring and to the severity of the crash consequences (25, 26).
- A 5% increase in average speed leads to an approximately 10% increase in crashes that cause injuries, and a 20% increase in fatal crashes (27).
- Pedestrians have a 90% chance of surviving a car crash at 30 km/h or below, but less than a 50% chance of surviving impacts of 45 km/h or above (27, 28).
- Safe speed thresholds vary according to different types of road, different types of collision and different road users, with their inherent vulnerabilities. Effective speed management needs to take these and other variables into account (27).
- Zones of 30 km/h can reduce crash risk and injury severity and are recommended in areas where vulnerable road users are particularly at risk (27, 29).
- Apart from reducing road traffic injuries and deaths, lowering the average traffic speed can have other positive effects on health outcomes (e.g. by reducing respiratory problems associated with car emissions) (27).

What this survey found

Research on effective speed management indicates that the speed limits on urban roads should not exceed 50 km/h. While there remains a fairly high fatality risk at this speed (or even lower for pedestrians, cyclists and other vulnerable road users), many countries with good road safety records have adopted this recommendation, while also giving provincial or local decision-makers the authority to reduce these national speed limits. In this way traffic calming measures

Box 3: A coordinated approach to road safety

The *World report on road traffic injury prevention* developed by WHO and the World Bank recommends that countries identify an agency with the authority and responsibility to make decisions and coordinate road safety activities across multiple sectors, and with adequate finances for road safety activities. The *World report* also recommends that each country should prepare a multisectoral national road safety strategy, with targets for the achievement of specific outcomes and with resources allocated to ensure implementation of relevant activities.

Although 153 countries (86%) report having a lead agency for road safety, this survey was unable to obtain information on the precise role or effectiveness of these agencies in fulfilling the functions required (see Table A.7 in Statistical Annex). Indeed, in the qualitative comments of the survey, respondents highlighted the considerable difficulty that they had during the consensus meetings in identifying the lead agency for road safety in their country.

The global survey also found that while 58% (n=103) of countries report having a national strategy on road safety, only 86 countries (48% of the total) have government endorsement of this strategy (see Table A.7 in Statistical Annex). Furthermore, only 34% (n=61) of countries have government endorsement of a strategy that has both precise targets and earmarked funding. These results suggest that the high positive responses obtained on lead agencies and national strategies may belie weaker institutional frameworks with insufficient financial resources to support either the effective functioning of these agencies, or the implementation of their activities.

Only 29% of countries have urban speed limits of 50km/h or below and allow local authorities to reduce them further.

Figure 6. Proportion of countries by urban speed limit range in 174 countries

that have been shown to be very effective at reducing road traffic injuries can be made and implemented at the subnational level as needed – for example in residential areas, or near schools. In the analysis of the results of this survey the criteria used for assessing urban speed management were therefore:

- speed limits on urban roads are set at less than or equal to 50 km/h;
- local authorities are able to lower these speed limits where necessary.

The results suggest that urban speed management is poor in many countries. While 62% of countries have speed limits on urban roads of less than or equal to 50 km/h, these countries account for half (50%) of the world’s population. Just over half (53%) of participating countries allow local authorities to reduce national speed limits (see Table A.5 in Statistical Annex). The global survey showed that only 29% of participating countries meet both these conditions – i.e. they have speed limits of 50 km/h or below on urban roads and they allow local authorities to reduce the national speed limits. Figure 6 shows the proportion of countries with different speed limit ranges, suggesting that in most countries additional efforts to reduce urban speed limits are still needed.

Furthermore, the results of the global survey show that only 9% of countries rate the enforcement of their national speed limits at more than 7 on a scale of 0 to 10 (see Table A.5 in Statistical Annex). This suggests that, even in countries where speed limits may be more restrictive, enforcement is frequently lacking.

WHAT CAN BE DONE

- ✓ Countries need to set speed limits that reflect the function of individual roads. In doing so, they should consider the types of vehicles using the road, the nature and purpose of the road, roadside activities, provision of facilities for vulnerable road users, and the frequency of use by pedestrians and cyclists. Increased priority should be given to vulnerable road users, notably in urban areas, where speed limits should not exceed 50 km/h.
- ✓ Local authorities need to be given the authority, resources and political support to implement measures to reduce speed limits to levels that may be lower than national limits where vulnerable road users are particularly at risk.
- ✓ Programmes put into place to address speeding need to foster a public awareness and understanding of the effects of speeding and the reasons for enforcing speed limits.

Drinking and driving

What is known?

- Drinking and driving increases both the risk of a crash and the likelihood that death or a serious injury will result (4).
- The risk of involvement in a crash increases significantly above a blood alcohol concentration (BAC) of 0.04 g/dl (30, 31).
- Laws which establish lower BACs (between zero and 0.02 g/dl) for young/novice drivers can lead to reductions of between 4% and 24% in the number of crashes involving young people (32).
- Enforcing sobriety checkpoints and random breath-testing can lead to reductions in alcohol-related crashes of about 20%, and has been shown to be very cost-effective (33, 34).

What this survey found

Ninety-six per cent (n=171) of participating countries report having either national or subnational laws on

drink-driving. However, only 88 countries (49%) have a drink-driving law that uses a BAC limit of less than or equal to 0.05 g/dl, as recommended in the *World report* (see Table A.3 in Statistical Annex). While most countries (86%) in the European region have BAC laws in line with this recommendation, in other regions of the world most countries either do not have BAC limits or have limits that are above 0.05 g/dl (see Figure 7).

Young or novice drivers are at a much increased risk of having a road traffic crash when under the influence of alcohol. Consequently, the *World report* advised that BAC limits for this group be set lower than limits for the general population. Only 19 of the 139 countries which have BAC limits for the general population have stipulated lower BAC limits for these young and novice drivers, and most of these countries are in the European Region.

Figure 7. Blood alcohol concentration limits (g/dl) by country/area

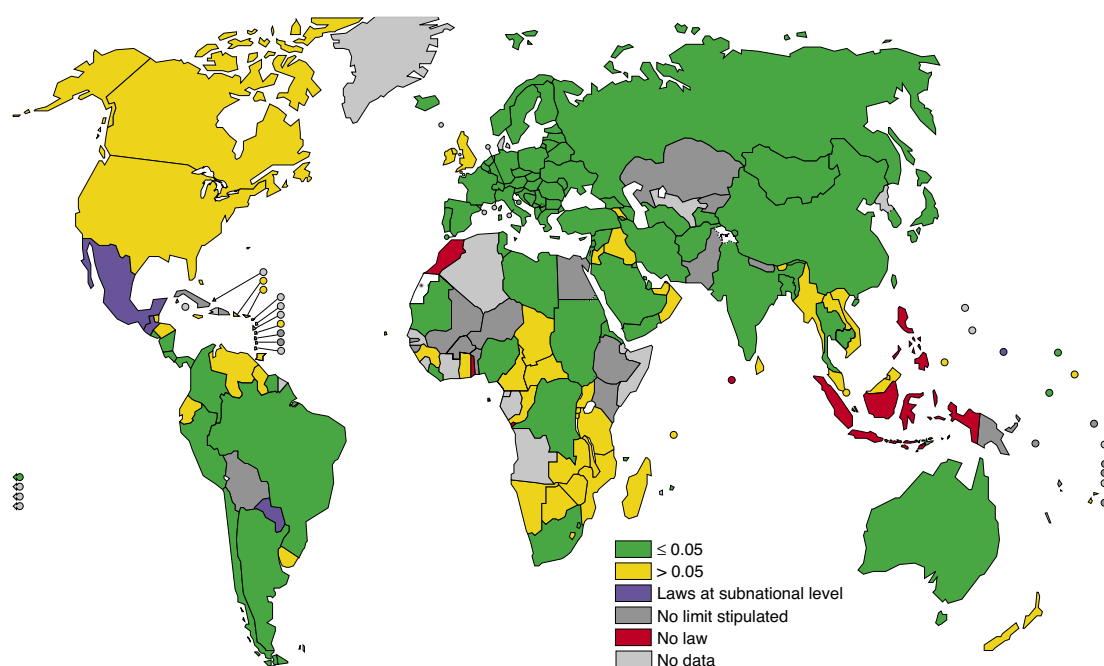

PHOTO LEFT Alcometers are part of the Mexican government's programme to reduce drink-driving.

CENTRE Helmets are effective at reducing the risk of head injuries but do not prevent a crash from occurring. Separating motorcyclists from other motorized vehicles is one way to reduce the likelihood of crashes involving motorcyclists from occurring.

RIGHT In Viet Nam, where children frequently ride motorcycles to and from school, a mandatory helmet-wearing law is accompanied by public awareness campaigns and extensive helmet distribution.

Photo © P. Orellana/WHO

Less than half of countries worldwide have drink-driving laws based on a blood alcohol concentration limit that is equal to or less than 0.05 g/dl.

Random breath-testing and police checkpoints are important enforcement mechanisms that have been shown to reduce alcohol-related crashes. Seventy-nine per cent of countries report that they use one or both of these methods of enforcement. However, only 23 countries (13%) report an enforcement rating of over 7 on a scale of 0 to 10 (see Table A.3 in Statistical Annex). This represents 21% of high-income countries, 11% of middle-income countries and just 9% of low-income countries. Taken together, these findings show that only 10% of participating countries, covering 24% of the world's population, have both adequate drink-driving laws (as defined by a BAC limit of less than or equal to 0.05 g/dl) and enforcement ratings of over 7.

WHAT CAN BE DONE

- ✓ All countries should have a drink-driving law and should strictly enforce it.
- ✓ Drink-driving laws should be based on blood alcohol concentration, or the equivalent breath alcohol content limits, which should be 0.05 g/dl or below.
- ✓ All countries should set limits of 0.02 g/dl or below for young/novice drivers.

Use of motorcycle helmets

What is known?

- Wearing a motorcycle helmet correctly can reduce the risk of death by almost 40% and the risk of severe injury by over 70% (35).
- When motorcycle helmet laws are enforced effectively, helmet-wearing rates can increase to over 90% (36, 37).
- The effectiveness of motorcycle helmets in reducing head injuries is in part a result of the quality of the helmets. Requiring helmets to meet a recognized safety standard is important to ensure that helmets can effectively reduce the impact of a collision to the head in the event of a crash (38).

What this survey found

Over 90% (n=163) of countries participating in this global survey have laws set at either the national or subnational level that require helmets to be worn by users of motorized two-wheelers. However, legislation is incomplete in many of these countries. For instance, some countries make exceptions for motorcyclists using low-

Photo © Public Works Department, Malaysia

Photo © M. Peleary/WHO

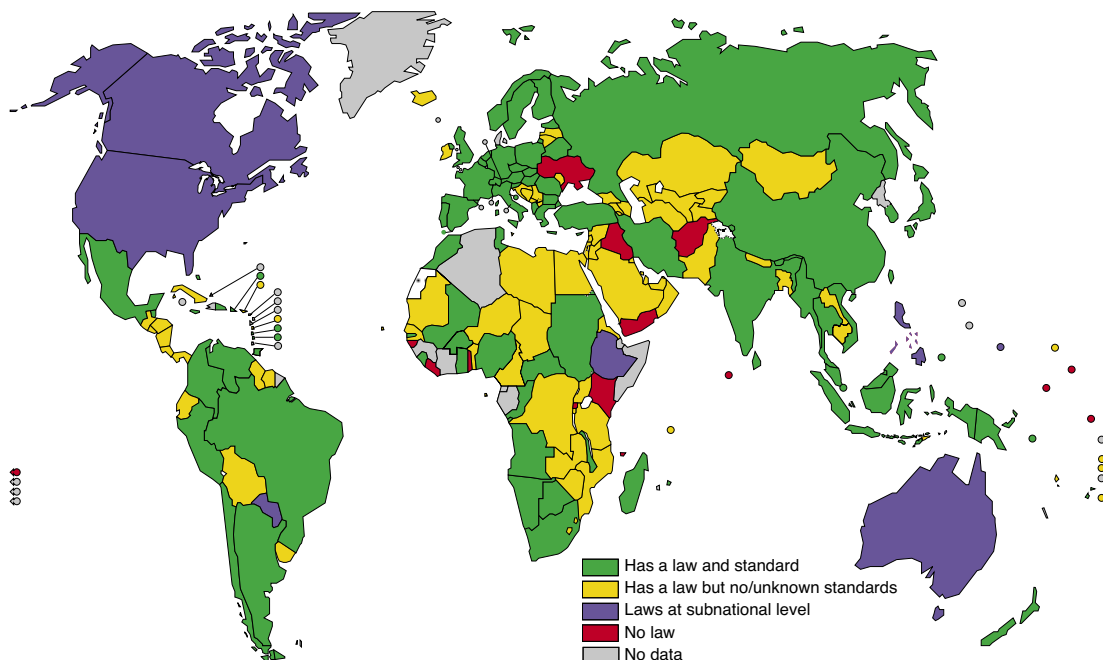

powered engines, while other countries exempt all passengers, or persons with religious headgear. This survey found that 74% of participating countries have helmet laws that are comprehensive in scope, i.e. that require both drivers and passengers of motorized two-wheelers to wear helmets on all roads and regardless of engine type¹ (see Table A.6 in Statistical

Annex). Furthermore, the results show that helmet standards are lacking in a high proportion (43%, n=76) of countries, thus calling into question the ability of a law on helmet-wearing to achieve its purpose. Taken together these findings mean that only 40% (n=70) of countries have comprehensive helmet laws *and* require helmets to meet a specific standard (see Figure 8).

Only 40% of countries have a comprehensive helmet law and require helmets to meet a specific standard.

¹ Some of these have exceptions, such as exempting those for medical reasons or for religious reasons.

Figure 8. Motorcycle helmet laws and helmet standards by country/area

Even where comprehensive laws are in place, enforcement is low in most countries. Only 25% (n=45) of countries rate their enforcement of helmet-use laws as higher than 7 on a scale of 0 to 10 (see Table A.6 in Statistical Annex). Finally, the impact of helmet laws that are in place is also difficult to ascertain in many countries. Only 34% of countries have data on helmet-wearing rates, and both the reliability and the generalizability of the results vary considerably (see page 35).

Seat-belt use

What is known?

- Wearing a seat-belt reduces the risk of a fatality among front seat passengers by 40–50% (39–41).
- Studies suggest that seat-belts can reduce fatalities among rear-seat car occupants by 25–75% (39, 42).
- Mandatory seat-belt laws, their enforcement, and appropriate public awareness campaigns have been shown to be very effective in increasing rates of seat-belt wearing (4, 39, 43).

WHAT CAN BE DONE

- ✓ All countries should have mandatory laws on helmet use on motorized two- and three-wheelers.
- ✓ These laws should cover all riders who are legally allowed to ride on motorized two- or three-wheelers, all engine types and all road types.
- ✓ Countries need to enact laws requiring helmets to meet a national or international standard.
- ✓ Countries need to establish systems to collect data on rates of helmet-wearing.

What this survey found

While seat-belt laws are widespread – with 88% (n=156) of countries participating in the global survey reporting national or subnational laws – in many countries the law does not apply to all car occupants (i.e. to front and rear-seat occupants). Only 57% (n=101) of countries require all car occupants to wear seat-belts, and this figure is much higher in high-income countries (76%) than in middle-income countries (54%) or low-income countries (38%) (see Table A.4 in Statistical Annex).

Only 38% of low-income countries and 54% of middle-income countries require seat-belts to be used in cars by both front-seat and rear-seat passengers.

Photo © NCHRP/CDC

Twelve per cent (n=21) of countries have no seat-belt law at all (see Figure 9).

Enforcement of seat-belt laws is weak in many countries. Only 19% (n=34) of countries rate enforcement of their seat-belt laws above 7 on a scale of 0 to 10. Only 14% of countries (n=25) have a seat-belt law that applies to all occupants and an enforcement rating of greater than 7 on a scale of 0 to 10 (see Table A.4 in Statistical Annex).

The ability to ascertain the effectiveness of these laws is difficult if relevant data are not available: in this survey over 47% of countries reported having no data on rates of seat-belt use in front seats, and 71% reported no data on rates of wearing rear seat-belts.

Seat-belt laws cannot be effective if large numbers of cars are not fitted with seat-belts, as is the case in many low-income countries. Although the survey

did not collect information on seat-belt requirements for imported cars, data from the survey show that of the 59 countries that manufacture or assemble cars, over one quarter (29%) do not require seat-belts to be fitted in both front and rear seats.

WHAT CAN BE DONE

- ✓ Vehicle manufacturers and assemblers should be required to fit seat-belts in both front and rear seats of all vehicles, irrespective of the end market.
- ✓ Seat-belt laws must be improved to cover all occupants.
- ✓ Enforcement efforts must be strengthened in many countries and must be equally applied to the occupants of both front and rear-seats in cars.
- ✓ Countries need to establish systems to collect data on rates of seat-belt use.
- ✓ Enforcement efforts must be backed by intensive mass-media education programmes that highlight the risk of injury when not wearing a seat-belt and increase the perceived likelihood of being detected and penalized.

Figure 9. Seat-belt laws by country/area

Use of child restraints

What is known?

- Children who are unrestrained in a car are at increased risk of injury and death in the event of a collision. Appropriate child restraint systems, which include child seats for infants and booster seats for older children, are designed with the child's developmental stage in mind. They work to secure the child in a way that reduces the chance of a severe injury occurring.
- If correctly installed and used, child restraints reduce deaths among infants by approximately 70% and deaths of small children by between 54% and 80% (39, 44).
- Mandatory child restraint laws and their enforcement lead to an increase in the use of child restraints (41, 44).

What this survey found

The global survey found that just under half of participating countries (n=87) report any legislation at all on the use of

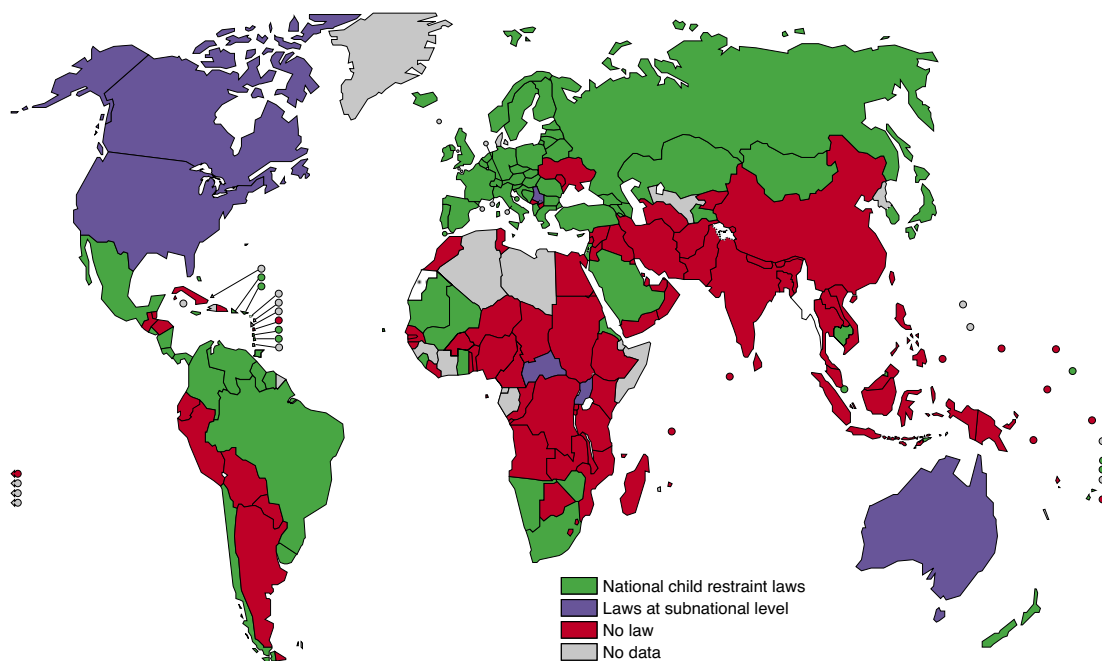

child restraints (see Figure 10). However, this figure hides considerable variation by region and income status (see Table A.4 in Statistical Annex). More than 90% of high-income countries have national legislation on child restraints, while the proportion in low-income countries is only 20%.

Even where legislation is in place, the results of the survey suggest that enforcement of child restraint laws is very low in most countries: only 14% of those countries with national legislation on the use of child restraints report enforcement as being above 7 on a scale of 0 to 10. This means that only 6% of all participating countries have a child restraint law *and* rate its enforcement as over 7 on a scale of 0 to 10 (and these are all high-income or middle-income countries). As well as weak legislation and poor enforcement, previous research indicates that the prohibitive cost of child restraints in many countries is also an important factor that affects usage.

Just under half of countries have a law requiring the use of child restraints for young children in vehicles.

Figure 10. Child restraint legislation by country/area

WHAT CAN BE DONE

- ✓ Child restraint laws need to be enacted and enforced. These laws should specify the type of restraint, the child’s age for which each restraint is appropriate, and the seating position.
- ✓ Mechanisms should be established to improve access to affordable child restraints.
- ✓ Countries need to establish systems to collect data on rates of child restraint use.
- ✓ Programmes to increase use of child restraints need to address social norms and encourage a culture of safety. The public needs to be aware of the safety benefits of using child restraints.

Legislation: summary

While positive steps towards enacting appropriate legislation have been taken in all regions of the world, much remains to be done.

Although all countries reported national or subnational legislation related to at least one of the five key risk factors (speed, drink–driving, helmets, seat-belts and child restraints) only 48% of countries have national or subnational laws relating to all five risk factors. In addition, legislation on risk factors is still incomplete in its coverage in many

(85%) countries. Where laws on these risk factors exist, they are often inadequately enforced – particularly in low-income and middle-income countries.

Governments need to enact and enforce comprehensive laws that require all road users to be protected by means of appropriate occupant restraints and to respect alcohol and speed limits that reduce the risk of a road traffic crash. These laws need to ensure that legal loopholes are avoided that could exempt particular road users. Enforcement efforts must be highly visible, well-publicized,

sustained, and implemented by the use of appropriate measures and penalties for infringement. Nongovernmental organizations and other civil society groups can play an important role in generating public and political support for evidence-based road safety measures.

Enforcement is most effective when supported by intensive public awareness campaigns that both highlight the safety benefits of complying with the legislation and also increase the perception of being detected and penalized when not complying with the law. As well as increasing awareness of the laws – and of the penalties for not respecting them – public awareness campaigns need to work towards building a culture of safety so that the general public are aware of the safety reasons behind these laws.

Few countries have reliable data on road traffic injuries

Data on the magnitude of the problem and the risk factors involved are essential to developing a systems approach to road safety. A comprehensive assessment of the magnitude of road traffic injuries should consider not only mortality but also non-fatal injuries and resulting disability, as well as the economic cost of road traffic injuries and the cost-effectiveness of interventions.

A number of other indicators can, if monitored accurately and regularly, provide essential information to governments in targeting their interventions and in evaluating the effectiveness of their current national road safety programmes. These include the proportion of road traffic deaths that are attributed to alcohol as well as helmet and seat-belt use rates.

Only 22% of all countries responding to the survey had:

- data on fatal and non-fatal road traffic injuries, plus
- estimates of the cost to the economy, plus
- data on monitoring and evaluation indicators such as rates of helmet and seat-belt use.

Data on fatalities

Comparing data across nations requires a standardized definition of a road traffic fatality. However, countries report a wide range of definitions for a road traffic death. These definitions use different time periods between a road crash and death and include or exclude different types of road users. The same definitions are also not always used consistently in the same country (4).

The current recommended definition of a road traffic fatality for harmonization of surveillance purposes is “*any person killed immediately or dying within 30 days as a result of a road traffic injury accident*” (45). The choice of 30 days was based on research which showed that most persons who die as a result of a crash succumb to their injuries within 30 days of sustaining them and that, while extension of this 30-day period resulted in a marginal increase in numbers, it required a disproportionately large increase in surveillance efforts (7).

Although there are moves within some regions to make this 30-day definition the standard, the results of this survey indicate that this goal remains largely unattained. The time periods used in definitions of road traffic-related deaths range from “died at the scene of the crash”, through a 7-day period and a 30-day period, to any death that results from a road traffic crash regardless of the time that has elapsed. At the global level

only 80 countries (45%) use a 30-day definition for a road traffic fatality (see Figure 11). Even within the European Region, which has made considerable efforts to bring countries in line with the 30-day definition of a road traffic fatality, there is wide variation. Although definitional issues can be overcome by applying correction factors, for harmonization and comparison purposes it would be easier if all countries used the same definition.

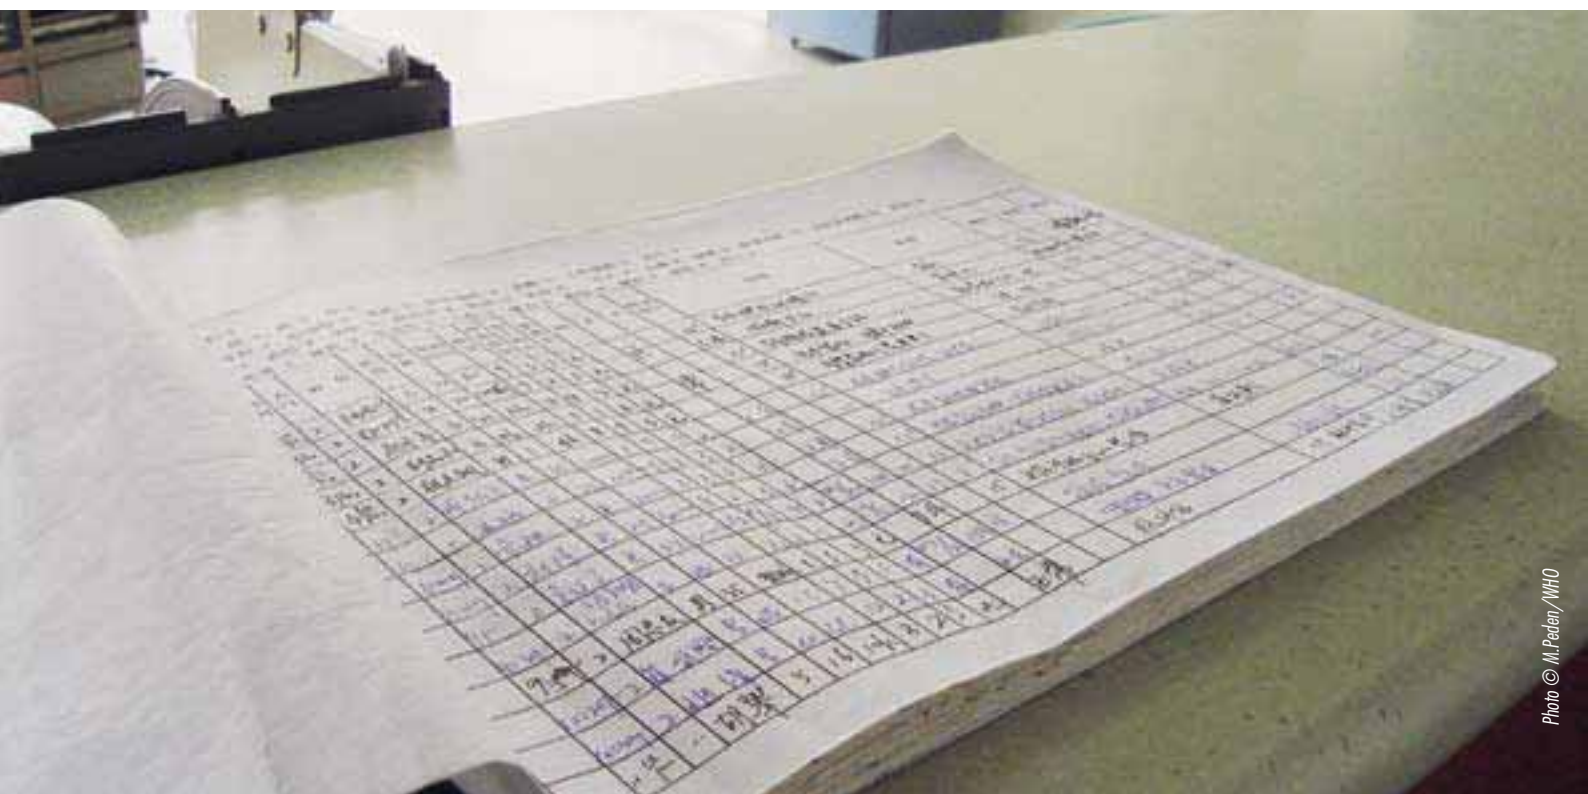

Underreporting has been acknowledged for many years as another important reason why it is difficult to compare road traffic crash data between countries. Some countries have taken steps to address this issue and to adjust their own data or link their different databases, but many have not. Factors that can affect the quality of data reported include political influences, competing priorities and availability of resources.

Figure 11. Time period used to define a road traffic fatality by country/area and income group

HIC = high-income countries; MIC = middle-income countries; LIC = low-income countries

Simple casualty registers can be used to obtain a minimum dataset which provides information on non-fatal injuries.

The extent of underreporting is also influenced by:

- the sector that records the information;
- the proportion of crashes involving vulnerable road users (in many countries these types of crashes are more likely to be underreported);
- poor or absent links between police, transport and health service data, which means that figures for people who die after admission to hospital may not be reflected;
- exemptions from reporting certain crashes, such as those involving non-motorized or military vehicles; and
- whether sampling strategies are employed and extrapolated.

Finally, an important factor in the quality of a country's health data in general is the equality of access of its people to health care facilities.

One way of improving this problem is to link data sources. Studies have shown higher levels of underreporting

in data collected by the police and transport sectors compared to health sector data, which suggests the need for links to improve data quality (46). This survey showed that only 14% of countries used health data as a source of their fatality information, either alone or in combination with data from another source (Figure 12). Half of the countries reported data on road traffic fatalities on the basis of police records only.

All the above complexities limit transnational comparisons. Consequently a number of mechanisms have been developed to try to address some of the issues of underreporting and to make data more comparable. In this global survey we used (a) the Smeed Coefficient (47) to adjust all countries' road traffic fatality data to a 30-day definition, and (b) developed a special model using negative binomial regression (see Statistical Annex for more information). Table 4 shows the reported data and rate per 100 000 population versus that obtained by the model, indicating a 46% difference globally.

Figure 12. Proportion of countries using different data sources for road traffic fatalities

Table 4. Road traffic deaths by WHO region using reported and modelled data

WHO REGION	REPORTED DATA ^a		MODELLED DATA ^a	
	<i>n</i>	RATE PER 100 000 POPULATION	<i>n</i>	RATE PER 100 000 POPULATION

GLOBAL	661 319	10.1	1 234 026	18.8

^a Adjusted for 30-day definition.

WHAT CAN BE DONE

- ✓ Encourage the use of the 30-day definition of road traffic fatality for harmonization across data sources.
- ✓ Improve data linkages between police, transport and health sectors.
- ✓ Increase human capacity to undertake data collection, analysis and interpretation.
- ✓ Improve the use of ICD¹ coding in vital registration to adequately reflect road traffic deaths.

¹ The International Classification of Diseases (ICD) is used to classify diseases and other health problems recorded on many types of records, including death certificates and health records. The most recent (10th) revision of the ICD codes came into use in 1994 but some countries still use previous versions.

Data on non-fatal injuries

In addition to mortality data, information on non-fatal injuries is important because it provides a complete picture of the impact of road traffic crashes for policy-making. It can, for example, guide hospital staffing, doctor and nurse training, and allocation of funds for hospital admissions and rehabilitation. However, it is not always essential to set up a sophisticated injury information system; when resources are scarce some type of “casualty register” or repeated surveys can be equally useful.

Problems relating to the quality and reliability of data on non-fatal injuries are probably even more complex than those relating to data on deaths. Reliable assessment of the severity of injury requires some clinical experience or medical expertise. A few countries

employ hospital staff to code injuries when the patient is discharged from care – using a standardized scoring method such as the Abbreviated Injury Scale, Injury Severity Score or the International Classification of Diseases codes – and then link these data to police/transport databases (48–50).

However, in many countries the level of severity of an injury is recorded by the police at the site of the crash. This results in less reliable categorization of injuries. The lack of harmonization in terminology used also makes country comparisons difficult. In some countries, “serious” is defined as “requiring hospital attention”, while in others it is “inpatient care for at least 24 hours”, while yet others have longer admission times. There is usually little liaison between the police and health facilities to track

PHOTO LEFT Training police in Addis Ababa on data collection is one measure used by the Ethiopian government to improve estimates of road traffic injury fatalities.

CENTRE A nurse attends to a motorcyclist with a head injury in Chiang Mai, Thailand.

RIGHT Remembering those killed in road traffic crashes in France.

The majority of countries do not have robust data on non-fatal road traffic injuries.

how long a patient is admitted for and so the category of serious can range from a few cuts and bruises to severe head injuries. To compound this, in most high-income countries those involved in a crash with any type of injury are usually seen in an accident and emergency room for insurance purposes, while in low-income and middle-income countries this depends on access to care, a good pre-hospital care system, finances, and other variables (see Box 4).

This survey showed a 1:20 ratio between deaths and severe injuries. If this were applied to the global total of 1.27 million deaths, it would mean that approximately 25.4 million people are injured severely enough to be seen in an emergency room. This supports previous estimates of the total number of non-fatal injuries (all severity levels) as between 20 and 50 million (4, 7).

WHAT CAN BE DONE

- ✓ The data collected by the health sector need to be improved. This is particularly true with regard to data on non-fatal injuries. This can take the form of discharge data using ICD coding, injury surveillance systems or, where this is not feasible, intermittent surveys or “casualty registers” which collect only minimum data (51).
- ✓ There is a need for standard definitions of levels of severity of non-fatal injuries to allow them to be accurately recorded and collated. The definitions should be simple enough to be administered by both health and non-health personnel.
- ✓ Countries should be encouraged to link all data sources on road traffic injuries in order to help address underreporting.

Box 4: Pre-hospital care

Much can be done to lower the burden of death and disability from road traffic injuries by strengthening trauma care services across the spectrum from pre-hospital care through to rehabilitation. The chain of survival starts at the scene of the incident. Prompt, good quality pre-hospital care can save the lives of many injured persons.

This global survey showed that 76% of the 178 countries have formal pre-hospital care systems. The quality of these systems, however, was not evaluated. They could range from sophisticated systems with highly qualified staff to those that rely only on first responders, e.g. bystanders.

The quick arrival of emergency response teams is an important factor in reducing adverse health consequences of a crash. Although most countries have one universal pre-hospital care access telephone number, 13 countries have up to three different national telephone numbers and a further 25 countries have local or region-specific numbers. This can be confusing for the lay person who has to remember the different numbers and then decide which number to use. For example, in South Africa if you are using a mobile phone you are required to dial 112, while on a landline the number is 10177. To compound matters, a number of private ambulance companies cannot be accessed unless one has medical insurance which covers this service.

The most common pre-hospital care access number used is 112 (used by 26 countries), followed by 911 (used predominantly in the Americas) and 999 (used predominantly in Africa) (see Table A.8 in Statistical Annex). As international travel increases, it will be increasingly important to work towards one global or regional phone number. For instance, the European Union is moving towards the adoption of one universal number (112) for all its member countries.

Photo © WHO

Where no pre-hospital trauma care system exists, trained community members can provide first aid.

Data on economic costs

Considerable economic and social costs result from deaths, injuries and disability caused by road traffic crashes. The survey results showed that:

- Less than half of all participating countries have conducted a study on the cost of road traffic deaths and/or injuries (see Table 5).
- Most surveys are not national but based on a sample and are usually conducted in a teaching hospital. Data drawn from them, while useful, therefore have limited generalizability.
- Gross output methodology is the most common method used to assess costs. While this type of costing is useful for health services, it shows only the tip of the iceberg. Loss of productivity, damages, reduced quality of life and other factors are important indirect costs that need to be included if the true cost to society is to be calculated.

- While country-level costing studies are important for internal comparisons, at a global level they have considerable limitations with regard to comparisons in terms of the different methodologies employed, the different currencies used and the different years in which the samples were collected.

However, this type of information at country level is extremely important for showing the impact of road traffic crashes on all the sectors involved and for convincing politicians to invest in prevention. Knowing the effectiveness of interventions and consequent cost-benefit ratios would be most beneficial to countries.

WHAT CAN BE DONE

- ✓ Countries should be encouraged to conduct national studies on the costs of road traffic crashes as well as on the cost-effectiveness of interventions they put into place.
- ✓ Where possible, costing should include both direct and indirect costs.

Data on monitoring and evaluation

Only 75 of the 178 countries surveyed (42%) have a national road safety strategy which includes targets. Over one-third of these countries are in Europe where a European Union target was set some years ago for achievement by 2010 (see Table 6). Other regions like Africa have also recently adopted targets although these have yet to be reflected at country level.

Targets are not the only method of monitoring or evaluating progress. Pages 18–28 describe the evidence on a number of proven interventions that are critical to improving road safety. These include reducing speed and drink-driving, and increasing the use of helmets, seat-belts and child restraints.

While some countries have put into place legislation to address these risk factors, few countries have established systems to collect data on monitoring or evaluating the success of these measures at a national level.

In this survey only 34% of countries reported data on motorcycle helmet-wearing rates, with the levels of helmet-wearing reported varying widely, as shown in Figure 13 and Table A.6 in the Statistical Annex. However, the methodologies used to determine these figures were not evaluated as part of this study, while for some countries the helmet-wearing rates reported were results of small studies in particular geographic areas, which limit their generalizability.

Levels of seat-belt wearing among front seat occupants were reported for 95 countries and range from under 10% to over 90% (see Figure 14 and Table A.4 in Statistical Annex). Limitations of the methodologies used are similar to those

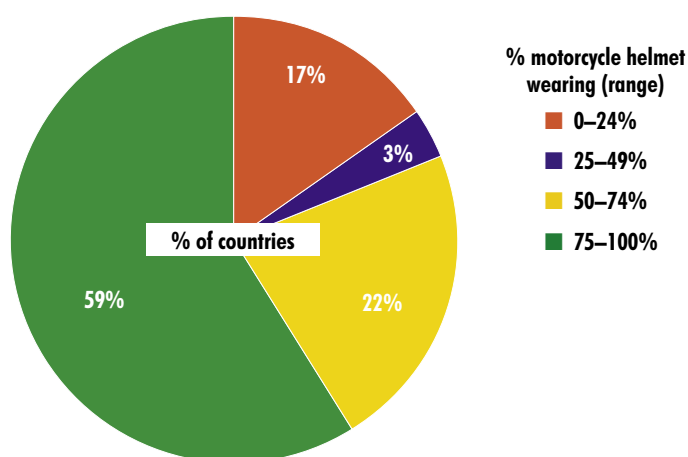

Table 6. Countries with targets included in their road safety strategies by WHO region and income level

WHO REGION	LOW-INCOME	MIDDLE-INCOME	HIGH-INCOME	TOTAL

GLOBAL	13	32	30	75

^a No high-income countries.

^b No low-income countries.

Figure 13. Levels of motorcycle helmet wearing in 60 countries^a

^a In 51 countries this estimate was based on an observational study, the source of which is noted in the country profiles. In 9 countries the estimated wearing rate is the opinion of the consensus group.

Figure 14. Seat-belt wearing rates in 95 countries^a

^a In 86 countries this estimate was based on an observational study, the source of which is noted in the country profiles. In 9 countries the estimated seat-belt wearing rate is the opinion of the consensus group.

of helmet-wearing data. Forty-seven per cent of countries reported having no data on rates of seat-belt use in front seats, and 71% reported no data on rates of wearing rear seat-belts.

The proportion of deaths related to alcohol reported in this study varies from countries where this figure is under 5%, to those where alcohol contributes to over

half of all road traffic fatalities (see Figure 15 and Table A.3 in Statistical Annex). However, only half of participating countries have any data on the proportion of road traffic deaths attributable to alcohol – and those that do frequently only have data from more sophisticated tertiary hospitals, which limits the possibility of making generalizations on the basis of the information.

Figure 15. Proportion of alcohol-related fatal crashes in 93 countries^a

^a In 90 countries this estimate was based on official data, the source of which is noted in the country profiles. In 3 countries the proportion given is the opinion of the consensus group.

WHAT CAN BE DONE

- ✓ Countries need to step up efforts to collect robust data on a number of intermediate indicators that relate to road traffic injury prevention and that can be used for monitoring and evaluation research. These include:
 - rates of helmet use;
 - rates of seat-belt use;
 - the proportion of drivers with blood alcohol concentration over the legal limit;
 - rates of child restraint use.
- ✓ While high-income countries often use sophisticated survey methodology, basic helmet and seat-belt wearing surveys are relatively simple and cheap to conduct. Surveys are essential for comprehensive monitoring to take place.
- ✓ These data are pivotal to making policy decisions based on evidence, and to evaluating measures that are put in place.
- ✓ The health sector should play an important role in research related to risk factors.

4

Conclusions

Strengths and weaknesses of this survey

This survey is a first step towards a broad global assessment of road safety. It brings together a unique set of data on a number of road safety variables for 178 countries, accounting for over 98% of the world's population. It brings road safety into line with other issues such as climate change, tobacco and tuberculosis, where regular

assessments allow countries to monitor their progress over time compared to that of other countries.

The survey methodology was designed to increase the accuracy and completeness of the data that were submitted to WHO, by requiring respondents from multiple sectors to take part and reach consensus on the final answers. An additional benefit of the methodology was to foster

multisectoral collaboration by linking road safety practitioners working in the same country. Some National Data Coordinators reported that the consensus group meeting was the first time that practitioners from different sectors had met to discuss road safety. As a result of the regional training workshops held as part of this project, networks of National Data Coordinators have been developed and are already being used to facilitate regional collaboration.

Nonetheless, as with any study, there are a number of limitations, namely:

- The comparability of data across countries is somewhat limited because of: different interpretations of terms used in the questionnaire (e.g. what constitutes a rural road or a highway differs between countries); countries reporting data from different years (2006 or 2007); and different sources of data used for variables (e.g. fatality data in some countries came from the police sector, and in others from the health sector, which has implications on completeness).
- The survey focused on national level data. This meant that, for the countries where risk factor legislation is enacted at the subnational level, the details on these variables were not recorded. Similarly, while many laws on road traffic-related risk factors are enacted at national level, enforcement and regulatory measures are often carried out at the subnational or local level.
- Finally, data collection in this project involved the use of self-administered questionnaires which can introduce a number of potential biases. In addition, a degree of subjectivity was introduced as respondents were asked to rate their *perception* of enforcement of the legislation on risk factors in their country.

Key messages and recommendations

This survey covered the magnitude of road traffic injuries as well as the existence of institutions, policies, legislation and data collection systems, and perceived levels of enforcement of legislation at a country level. The main findings are summarized as follows:

- Road traffic fatalities remain a major public health problem, with the highest fatality rates per 100 000 population in middle-income and low-income countries. Pedestrians, cyclists, and users of motorized two- or three-wheelers (“vulnerable road users”) together account for approximately half of all road traffic deaths around the world. Vulnerable road users are particularly at risk in low-income and middle-income countries in Asia.
- While many countries have a basic legislative framework in place for road safety, only 47% have laws relating to all the five key risk factors reviewed – speed, drink-driving, helmets, seat-belts and child restraints. Furthermore these laws are frequently not comprehensive in their scope.
- Enforcement of laws relating to these risk factors for road traffic injuries is perceived to be suboptimal in many countries.
- Institutional frameworks are insufficiently developed or resourced in many countries to be effective. For instance, while 76% of countries report the existence of a national road safety strategy, only one-third of countries report government endorsement of the strategy that has both precise targets and sufficient funding for its implementation – both of which are important for the success of a strategy.

- There are several limitations in the data that countries collect and report on road traffic injuries. Underreporting of road traffic deaths – a crucial indicator in terms of assessing magnitude – is a major problem in many countries. In addition, only 22% of all countries indicated that they had data on fatal and non-fatal road traffic injuries, estimates of the cost to their economy, and data on monitoring and evaluation indicators such as rates of helmet use and seat-belt wearing.
4. Countries need to encourage collaboration among different sectors involved in collecting and reporting road traffic injury data. This involves improving data linkages between police, transport and health services, harmonization of case-definitions, as well as increasing human capacity to undertake data collection.

The results presented suggest that while most countries have taken steps towards addressing road safety, additional efforts are needed:

1. Governments need to take into consideration the needs of all road users when making policy decisions that impact on road safety. To date, the needs of vulnerable road users have been neglected in many countries and should be given renewed emphasis, particularly when decisions are made about road design and infrastructure, land use planning and transport services.
2. Governments need to enact comprehensive laws to protect all road users by setting speed limits that are appropriate to the type and function of the road, stipulating blood alcohol concentration limits that help reduce drink-driving, and requiring the use of appropriate protection measures. Existing legislation should be reviewed and amended to conform with good practices that are based on sound evidence of effectiveness.
3. Enforcement of all road safety laws needs to be improved. Enforcement efforts must be well-publicized, sustained, and implemented through the use of appropriate measures and penalties for infringement.
5. Governments need to ensure that the institutions that have been nominated as responsible for taking action on road safety have the necessary human and financial resources to act effectively. The evidence suggests that the development and endorsement of a national strategy with realistic targets and earmarked funding for implementation are important factors towards meeting long-term road safety goals.

The results of this survey can be used as a tool to inform policy decisions in conjunction with other international and national studies and programmes – for example, the United Nations Regional Commissions’ project on setting road traffic casualty reduction targets, or alongside implementation and evaluation of the good practice manuals developed through the United Nations Road Safety Collaboration. The results can also be used to leverage political support and resources for safer road transportation for all road users, including in international forums. One key milestone in international road safety events will be the First Global Ministerial Conference on Road Safety to be held in Moscow in November 2009. During the Conference, delegates are likely to call for a *Decade of Action*

on Road Safety. Should this proposal be endorsed by member countries, such a decade could be an important opportunity to further catalyse action. The results of this *Global status report* and the gaps it has identified should serve as key elements in the discussions during the Ministerial Conference on Road Safety as well as for planning the activities envisaged in the context of the *Decade of Action*.

An increasing body of research demonstrates ways to prevent crashes or to reduce the severity of injuries when they

do occur, and countries have taken many steps towards putting in place evidence-based interventions to make roads safer. At the international level, high-level commitment has been evidenced by various international resolutions and collaborative projects. This survey shows, however, that much more remains to be done. No country can afford to sit back and assume that its road safety work is complete, and the international community must continue to recognize road traffic injuries as an important health and development issue and intensify support for their prevention.

Country profiles

1. Explanatory notes

- Background
- Methodological variations
- Terminology and interpretation
- Presentation of data

2. Individual country profiles (listed alphabetically)

Explanatory notes

Background

The country profiles in this section present a selection of information about road safety as reported by each of the 178 participating countries/areas. Additional national data can be found in the Statistical Annex (Tables A.2 – A.7). The country survey tools may be downloaded from the following website: www.who.int/violence_injury_prevention/road_safety_status/2009

Methodological variations

One hundred and seventy-eight countries/areas participated in the survey for the *Global status report on road safety* (see Table 2 on page 10). While most countries/areas followed the standardized methodology (see pages 8–10 for more details), in eight of them (Australia, Germany, Kazakhstan, Puerto Rico, Saint Vincent and the Grenadines, Singapore, Ukraine and Uzbekistan) the questionnaire was completed by the National Data Coordinator (NDC) (see Table A.1 in Statistical Annex) and no consensus meeting was held. In addition, in all countries/areas of the WHO Eastern Mediterranean Region, the questionnaire was not self-administered but was completed through face-to-face interviews between the NDCs and individual respondents. Consensus meetings were, however, held in these countries/areas in accordance with the project methodology.

Data are reported for population, income group and gross national income per capita for the latest year available (see explanatory notes in the Statistical Annex for more details).

Terminology and interpretation

The following terms and issues should be considered when reviewing the individual country profiles:

- The questionnaire asked for information on a number of topics, with follow-up questions exploring each topic in further detail. For many topics respondents were asked to skip **follow-up questions** depending on their answer to the top-level question. Consequently, the country profiles do not report information from follow-up questions if these should have been skipped. However, if these questions were answered the responses are recorded in the Statistical Annex.
- **Road classifications** (in particular the definition of an urban road, a rural road and a highway) vary greatly from country to country. Respondents were asked to report on the speed limits of different kinds of road according to the definitions used in the country concerned.
- Respondents were asked, as individuals, to rate the **effectiveness of enforcement** of various elements of national road safety legislation on the basis of their professional opinion or perception. A scale of 0 to 10 was used, where 0 was “not effective” and 10 was “highly effective”. The group of respondents then tried to reach consensus on an enforcement score. These scores are therefore subjective and should be seen only as an indication of how enforcement is perceived in the country. Many respondents expressed difficulty in assessing law enforcement at a national level since it often varies from region to region within a country and the intensity of the enforcement may vary at different times.
- **Blood alcohol concentration (BAC) limits** refer to the maximum amount of alcohol that is legally acceptable in the blood of a driver on the road – i.e. the blood alcohol level above which a driver may be punished by law. For the purposes of this report, the BAC limit in countries where alcohol consumption is prohibited has been recorded as zero with an explanatory footnote.

- Where respondents provided explanatory information on **rates of helmet wearing and/or seat-belt use** – for instance, a description of the methodology or geographical coverage – this information is reported in footnotes.
- A **motorcycle helmet law** is assessed as “applies to all riders – yes” if the law requires drivers and passengers (both adults and children) to wear a helmet. Laws with exceptions on the grounds of religion, medical conditions or other reasons are indicated with the footnote “some exceptions”.
- Respondents were asked to report on **vehicle standards** required for car manufacturers or assemblers in the country. Therefore no information is included on vehicle standards for countries where manufacture or assembly do not take place. Some countries apply stringent standards to imported vehicles but data on such standards were not collected as part of this survey.
- Variables have been coded “Data not available (-)” if the information was not provided through the national data collection process.

Presentation of data

Country profiles contain **data** on road traffic fatalities and non-fatal injuries as **reported** by countries/areas.

- Data from different countries are not necessarily comparable, as different definitions and time frames have been used.
- Due to space constraints in footnotes, the data source has been summarized as Police, Transport or Health if the data are from the Ministry of Interior, Ministry of Transport or Ministry of Health, respectively.
- The proportion of deaths where the sex is unknown has not been reported in the profiles.

In the charts presenting data on **deaths by road user category**, proportions may not sum to 100% due to rounding. Some countries classify road traffic fatalities according to the vehicle or road user “at fault” rather than according to who died, or use categories different from those requested in the questionnaire. In these countries deaths among vulnerable road users are even more likely to be underreported.

The standard colour coding of the **pie charts** used to represent the road user categories requested in the questionnaire is shown below. Additional categories are represented by non-standard colours.

- | | |
|---|---------------|
| ● Drivers of 4-wheeled vehicles | ● Cyclists |
| ● Passengers of 4-wheeled vehicles | ● Pedestrians |
| ● Occupants (drivers/passengers) 4-wheeled vehicles | ● Other |
| ● Riders (drivers/passengers) of motorized 2- or 3-wheelers | ● Unspecified |

Trend graphs are shown either as road traffic death rates per 100 000 population (on a green background) or as an absolute number of road traffic deaths (on a blue background), depending on which figures were supplied by the country. Due to space constraints, an arbitrary cut-off point of 1970 was applied to the few countries that provided many decades of trend data.

Where the **primary source of information** for both the pie and trend graphs was not stipulated, the source has been reported as ‘Country questionnaire’.

Information about the number of vehicles in the country includes only **registered vehicles**, and proportions of various types of such vehicles. These proportions may not sum to 100% due to rounding. In some countries, respondents noted that a substantial proportion of the vehicle fleet may not be registered.

AFGHANISTAN

Population: 27 145 275

Explanatory notes

Background

The data presented in the following pages were obtained through a self-administered questionnaire implemented in the 178 countries and areas that participated in the first global survey on road safety in 2008. The survey focused on the recommendations of the *World report on road traffic injury prevention (1)* as the basis for its structure and content. Most countries used the same methodology for data collection, as outlined in a survey protocol developed for the study. In over 95% of the countries, the implementation of the survey was coordinated by a National Data Coordinator (NDC) identified by the country, and was completed by teams of 6–8 key respondents including the NDC. The NDCs were trained in the methodology and coordinated the collection, validation and clearance of data, as well as the data entry, in the countries concerned. The survey instrument, protocol and accompanying guidelines and training materials were all available in the six WHO languages (Arabic, Chinese, English, French, Russian and Spanish). Where needed, NDCs coordinated the translation of these documents into the local language and then back-translated them for the data entry which was done in English. More details on the methodology used for data collection can be found at www.who.int/violence_injury_prevention/road_safety_status/2009.

The following sections contain country-by-country data obtained from the survey.

- Table A.1 includes the list of NDCs who, in collaboration with national authorities, played a key part in conducting the survey.
- Table A.2 provides detailed data on the 30-day adjusted number and rates per population of road traffic deaths, and on the proportion of road users by country/area. The table also includes modelled road traffic death numbers which have been generated. A short description of the process is presented below.
- Tables A.3–A.6 provide information on the status of laws, the enforcement of laws, and the coverage/wearing rates relating to the five road traffic risk factors (alcohol, seat-belts, child restraints, speed, and helmets).
- Table A.7 contains data on policy-related responses.
- Table A.8 includes information related to the availability of pre-hospital care.

The following section gives a brief description of the data processing, the comments on the obtained results (specifically on the reported, adjusted and modelled country-level death data) and the method used to develop the model.

Data processing

The data processing involved completion of the survey instrument and data entry at a country level, and validation at a regional level. Data cleaning, analysis and report-writing were done at WHO headquarters in Geneva.

Reporting of country-level data

The final country responses were entered by NDCs into an online database specially prepared by WHO for this project. NDCs also uploaded supporting documents where applicable and available. Data were then validated at a regional level. Once finalized and approved by Regional Data Coordinators (RDCs), the data were then exported into Microsoft Excel for cleaning. At this stage, each country's data were examined for accuracy, consistency and validity on a question-by-question basis. Where necessary, NDCs were contacted and additional supporting documents were requested to clarify inconsistencies. A copy of the survey instrument and study protocol can be found at www.who.int/violence_injury_prevention/road_safety_status/2009.

As part of the data cleaning and validation process, exploratory analysis was done using STATA (2). The same software was used for all analysis and results presented in the earlier sections of this report.

Types of data utilized

Three types of data are used in this report:

- reported data from countries and secondary sources;
- data adjusted for the 30-day definition of a road traffic death in order to facilitate comparability;
- modelled numbers.

Reported data

In addition to the data obtained directly from countries, secondary data sources were used to:

- classify countries into income categories;
- generate road safety indicators such as the adjusted road traffic deaths and modelled road traffic death rates (with a 90% confidence interval) as reported in Table A.2.

Population and income data from the United Nations Population Division (3) and the World Bank (4) were used for this analysis.

Population estimates for 2007 are reported in Table A.2. Where there was no estimate available for a country for that year, published data for the latest year were used. For the modelling process, population estimates corresponding to the year of reporting were used (4).

In Table A.2, World Bank (Atlas method) gross national income per capita (GNI) for 2007 (5) (or latest available year) was used to categorize countries into:

- low-income = \$935 or less;
- middle-income = \$936 to \$11 455;
- high-income = \$11 456 or more.

More detailed subgroupings were used in the modelling process.

Adjusted data

As discussed in the first section of this report (see page 28), underreporting has been acknowledged for many years as an important reason for the difficulty in comparing road traffic crash data between countries. Additionally, the lack of harmonized definitions for road traffic deaths, the use of different data sources, and the quality of the reporting system have also been documented. Consequently a number of mechanisms were employed to address some of these issues in order to make data more comparable. This global survey employed the following two methods:

- the European Conference of Ministers of Transport (ECMT) standardized 30-day road crash fatality factors (6) to adjust all reported country/area data;
- a model using negative binomial regression (see page 233).

The “reported” data in Table A.2 have been adjusted to this 30-day definition (see Table 1 for adjustment factors) and the new adjusted number is therefore used in the corresponding model and its result is presented in Table A.2.

Table 1. ECMT standardized 30-day road crash fatality adjustment factors

	30-DAY TOTAL	ADJUSTMENT FACTOR
ON THE SCENE/1 DAY	77%	1.30
3 DAYS	87%	1.15
6 DAYS	92%	1.09
7 DAYS	93%	1.08
30 DAYS	100%	1.00
365 DAYS	103%	0.97

Modelled data

Developing a model

Before the modelling exercise, simple exploratory analyses were done to evaluate the distribution of the reported data, to identify potential outliers and to determine the extent of missing data. Decisions as to whether to include these outliers in the analyses, or whether to exclude them, were taken at several stages of the analysis. Where appropriate, imputation was done to compensate for missing information.

Completeness of data

Having adjusted the reported data to a 30-day definition to facilitate comparability, the next step in the process was to explore the completeness of the reported death data on the basis of reported vital registration (VR) data. Information on the completeness of VR data was obtained from previous WHO published reports (7, 8) and was updated with the latest information from the WHO mortality database. This information was then used to classify countries into two groups, namely:

- Group 1: countries with VR completeness greater or equal to 85% and external causes of death coded to undetermined intent less than 30% (Table 2);
- Group 2: countries with VR completeness less than 85% or external causes of death coded to undetermined intent greater than 30%.

Group 1 countries include 37 high-income, 36 middle-income and 2 low-income countries (Table 2). Data from these countries were used as a reference in constructing the negative binomial model. As such, no estimation was done for these countries.

Group 2 countries include 3 high-income, 48 middle-income and 43 low-income countries. Estimated data based on the prediction model described above are provided for these countries.

Countries/areas with populations of less than 100 000 and which thus have low numbers of deaths were also excluded from the modelling process (Table 3).

Table A.2 gives the 30-day adjusted number of deaths for all countries, and for group 2 countries the modelled number of deaths with a 90% confidence interval. Those without a range are Group 1 and the countries in Table 3 where no modelling was done.

Variables used in the model

Table 4 summarizes the independent variables used in the model and the data source.

Table 4. Independent variables used in modelling process

VARIABLE	SOURCE OF INFORMATION	COMMENTS
Income (GNI)	World Bank (4,5)	
Income level	World Bank (5)	Grouping used: low, middle, lower middle, upper middle, high. Designation based on 2000–2004 World Bank data, corresponding to year of income level used
Population		Estimated figures from UN Population Division (3)
Vehicle density: Number of cars per population	Number of vehicles: This GSRRS survey Population: World Bank (3)	
Road density: Total road per land area	2000–2006 World Road Statistics, International Road Federation, 2008 (9)	Total road/land km ² Corresponding or latest year data
Existence of national helmet law	This GSRRS survey	WHO questionnaire
National policies that encourage walking and/or cycling	This GSRRS survey	WHO questionnaire
National policies that support investment in public transport	This GSRRS survey	WHO questionnaire
National speed limits on urban roads	This GSRRS survey	WHO questionnaire
National speed limits on rural roads	This GSRRS survey	WHO questionnaire
Alcohol consumption	World Health Statistics, 2008 (10)	Alcohol consumption among adults aged ≥15 years for 2003
Strength of health system	World Health Statistics, 2008 (10)	Hospital beds (per 10 000 population)

GSRRS = Global Status Report on Road Safety
GNI = Gross National Income per capita

Estimation method

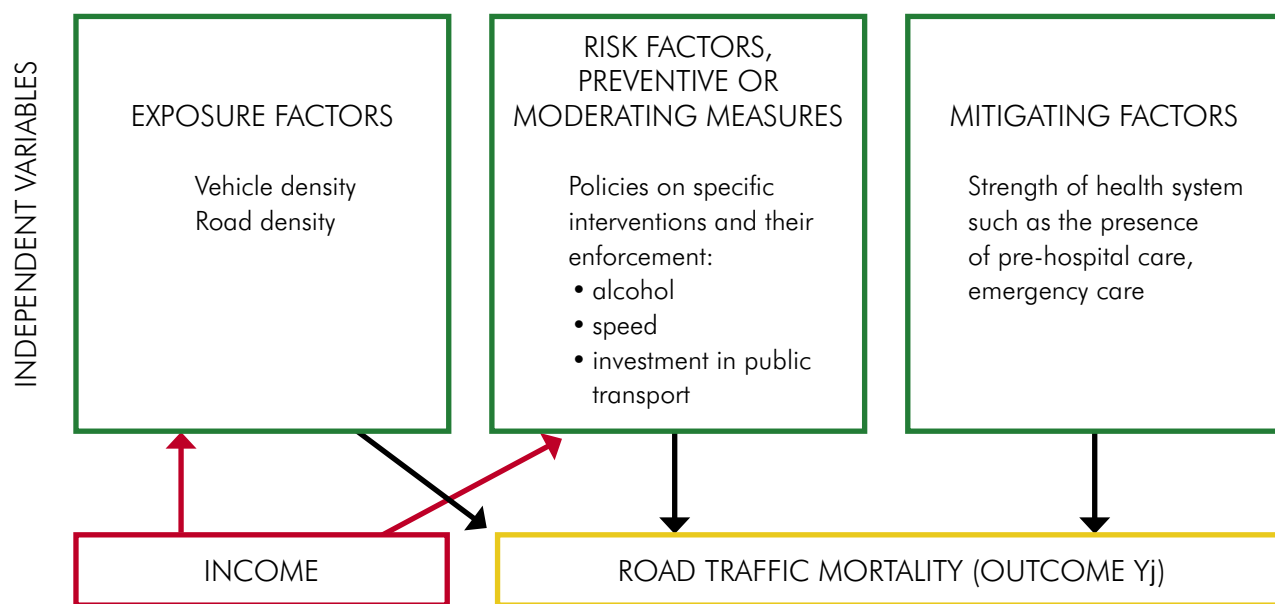

The third stage used data from Group 1 countries to develop a statistical model to predict road traffic deaths (point estimates) for Group 2 countries including 90% confidence limits. The framework used to predict road traffic mortality was constructed using selected variables (identified through a literature review) which have direct relationship to the outcome variable (road traffic death). These variables were later grouped into three categories: exposure factors (E_j), risk or preventive factors (R_j), and mitigating factors (M_j). Gross national income (I_j) has an influence on the first two categories (Figure 1).

In this framework, the road traffic mortality outcome (Y_j) is a function of a set of independent variables described as exposure factors (E_j), risk or preventive factors (R_j), mitigating factors (M_j) and gross national income (I_j). This can be expressed as follows: $Y_j = f(R_j, M_j, I_j, E_j)$.

The relationship between the outcome and the independent variables is a nonlinear function. The number of deaths (Y_j) is a non-negative integer count data; thus the standard approach (11) to be used is the Poisson regression or another form of regression based on the Poisson. The most commonly used regression model for count data treats the response Y as a Poisson variable. In the Poisson regression model, the mean equals the variance, conditional on explanatory variables. In practice, however, this assumption was not satisfied. For this reason, a negative binomial regression model was chosen where the assumption for the dependent variance and Poisson's particular case of negative binomial model are adequately satisfied.

Figure 1. Framework for determinants of road traffic mortality

DETERMINANTS OF ROAD TRAFFIC MORTALITY

At the end, a negative binomial regression modelling technique using STATA software (2) was used to predict the number of road traffic fatalities with population size as an exposure factor. The model was constructed on the basis of reported data from the 75 Group 1 countries/areas mentioned in Table 2.

The full in-depth description of the methodology and formulas for the modelling process are available at the following website: www.who.int/violence_injury_prevention/road_safety_status/2009

^a Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2007). *World population prospects: The 2006 revision, highlights*. New York: United Nations.

^b Gross National Income (GNI) per capita is the dollar value of a country's final income in a year divided by its population using Atlas methodology. Data from World Development Indicators database, World Bank, revised 17 October 2008.

^c World Development Indicators database: Low-income is \$935 or less, middle-income is \$936 to \$11 455, high-income is \$11 456 or more.

^d Adjusted for 30-day definition of a road traffic death.

^e Modelled using negative binomial regression. Data from countries with complete vital registration and countries with a population of less than 100 000 were not included in the model (see explanatory notes on page 231).

^f 2007 data not available. Latest available used from <http://data.un.org/>

^g Passengers and drivers of any motorized vehicle; includes category "unspecified".

^h Non-member area.

ⁱ For capital city only.

^j Associate WHO Member State.

^k Cyclists and pedestrians.

— Data not available.

ROAD TRAFFIC DEATHS				ROAD USER DEATHS (%)
